UPARIS-DS: Uncertainty-Aware Paragraph-Level Iterative Reflective Deep Search

A Multi-Agent Framework for Reliable Deep Research with Iterative Reflection and Uncertainty Quantification

---

Abstract

Large Language Models (LLMs) have demonstrated tremendous potential in automated research tasks. However, critical challenges including hallucination, incomplete information, and insufficient knowledge integration severely limit their reliability. This paper presents **UPARIS-DS** (Uncertainty-Aware Paragraph-Level Iterative Reflective Deep Search), a multi-agent deep research system built upon the **MARDS-v2** framework. The system introduces two core innovations: **Paragraph-Level Iterative Reflection** and **Uncertainty Quantification**, enabling high-quality, structured research report generation. UPARIS-DS employs an eight-agent collaborative architecture comprising specialized modules for structure planning, paragraph retrieval, summarization, reflection evaluation, content updating, global uncertainty computation, and final formatting. The system innovatively introduces the **Reflection Pressure Model**, which dynamically determines whether to trigger supplementary retrieval based on confidence levels, progressively reducing both paragraph-level and global uncertainty through multi-round iteration. Experiments demonstrate that compared to baseline methods, UPARIS-DS achieves 23% and 18% improvements in NDCG and MRR metrics respectively, reduces global uncertainty by 35%, and effectively reduces hallucination rates while enhancing reliability in multi-source knowledge integration.

Keywords: Multi-Agent Systems; Iterative Reflection; Uncertainty Quantification; Paragraph-Level Reasoning; Deep Search; Reliability Enhancement

---

1. Introduction

1.1 Background and Motivation

The rapid development of Large Language Models (LLMs) has made automated research report generation increasingly feasible. However, existing LLM-based research systems face the following core challenges:

1. **Hallucination**: LLMs tend to generate content that appears plausible but contains factual errors, severely impacting research reliability
2. **Incomplete Information**: Single retrieval rounds struggle to cover all aspects of complex research topics
3. **Insufficient Knowledge Integration**: Lack of effective mechanisms to integrate multi-source heterogeneous information and identify conflicting viewpoints
4. **Uncertainty Unawareness**: Systems cannot evaluate the credibility of their own outputs, making it difficult for users to assess result quality

While traditional Retrieval-Augmented Generation (RAG) methods introduce external knowledge, they remain limited in the following aspects: - Lack of deep understanding and reflection capabilities - Inability to identify boundaries and blind spots of own knowledge - One-shot retrieval patterns cannot guarantee information completeness and accuracy

1.2 Problem Definition

This paper aims to address the following research questions:

- **RQ1**: How to design an intelligent research system that can **self-evaluate, identify knowledge blind spots**, and **actively seek supplementary information**?

- **RQ2**: How to implement **iterative reflection** at the **paragraph level** so that each research section achieves high-quality standards?
- **RQ3**: How to introduce an **uncertainty quantification mechanism** that enables the system to reliably assess the credibility of its outputs?

1.3 Contributions

The main contributions of this paper are as follows:

1. **Proposed UPARIS-DS Framework**: The first multi-agent deep research system that integrates paragraph-level iterative reflection with uncertainty quantification
2. **Designed Reflection Pressure Model**: Dynamically determines whether to trigger supplementary retrieval based on confidence thresholds, achieving intelligent budget allocation
3. **Implemented Eight-Agent Collaborative Architecture**: Specialized division of labor including structure planning, retrieval, summarization, reflection, updating, global uncertainty computation, and formatting
4. **Constructed Complete Uncertainty Quantification System**: Including paragraph-level confidence, source quality scoring, evidence strength assessment, and global uncertainty aggregation
5. **Developed Quantifiable Quality Evaluation Metrics**: Integrated multi-dimensional evaluation including NDCG, MRR, source diversity, and reflection depth

---

2. Related Work

2.1 LLM-Based Research and Reasoning Systems

ReAct (Reasoning + Acting), proposed by Yao et al., achieves superior generalization across diverse tasks by interleaving reasoning traces and action sequences. However, ReAct employs a single-agent architecture lacking dedicated reflection mechanisms to evaluate and correct its own outputs.

Reflexion (Shinn et al., 2023) introduces verbal reinforcement learning, enabling agents to learn from failures. Reflexion maintains a "reflection memory" to avoid repeating errors, but its feedback mechanism is relatively simple and lacks systematic evaluation of information completeness.

Self-Refine (Madaan et al., 2023) proposes an iterative refinement paradigm that improves output quality through "generate-feedback-refine" cycles. However, Self-Refine similarly lacks uncertainty quantification and multi-agent collaboration mechanisms.

S3 (Search-Inference Switching) and **Search-Augmented Factuality Evaluator (SAFE)** attempt to enhance factuality through external retrieval, but have not formed a complete paragraph-level reflection framework.

2.2 Multi-Agent Systems for Knowledge Tasks

Multi-agent systems have shown significant advantages in knowledge-intensive tasks. **ChatDev** adopts a virtual software company model for software development, decomposing complex tasks through role-playing and communication protocols. **MetaGPT** further introduces metaprogramming concepts, treating agents as "software engineers" rather than simple executors.

In research tasks, systems like **DeepLab** and **ResearchGPT** attempt to integrate retrieval and generation, but generally lack: fine-grained paragraph-level processing, systematic reflection evaluation mechanisms, and quantifiable uncertainty indicators.

2.3 Uncertainty Quantification in LLMs

Uncertainty quantification is crucial for trustworthy AI systems. **Self-Consistency** estimates confidence by sampling multiple reasoning paths and aggregating results. **TruthfulAI** and **FactScore** are dedicated to evaluating the factuality of LLM outputs.

In RAG systems, evaluation frameworks like **RAGAS** and **ARES** attempt to measure retrieval and generation quality, but lack deep uncertainty assessment of generated content itself.

2.4 Comparative Analysis

Method	Multi-Agent	Paragraph Reflection	Uncertainty Quantification	Iterative Retrieval	Source Diversity
ReAct	×	×	×	×	×
Reflexion	×	✓	×	✓	×
Self-Refine	×	✓	×	✓	×
Traditional RAG	×	×	×	×	✓
UPARIS-DS	✓	✓	✓	✓	✓

3. Methodology

3.1 System Overview

UPARIS-DS is built upon the **MARDS-v2** framework, with the core design philosophy of achieving **reflectable, quantifiable, and improvable** deep research through multi-agent collaboration. The overall system architecture is illustrated in Figure 1.

```

Figure 1: UPARIS-DS System Architecture

3.2 Eight Specialized Agents

UPARIS-DS defines eight specialized agents, each undertaking specific responsibilities:

3.2.1 StructurePlannerAgent

Responsibility: Decompose user queries into structured report outlines

Input: `query` (user research query)

Output: `ReportStructure` (containing title, objective, and section list)

Algorithm Flow:

```
Algorithm 1: Structure Planning
Input: query
Output: sections[]

1. sub_questions  LocalDecompose(query)
2. prompt  RenderPrompt("structure_planner", query)
3. llm_output  DeepSeek.Chat(prompt)
4. sections  ParseSections(llm_output)
5. if |sections| < 5 then
6.     sections  sections  GenerateDefaultSections(5 - |sections|)
7. end if
8. return sections
```

3.2.2 SectionRetrieverAgent **Responsibility**: Retrieve diverse, high-quality authoritative information sources for each section

Core Innovations: - **Query Variant Generation**: Generate multiple query variants to increase retrieval coverage - **Diversity Filtering**: Ensure at most one result per domain - **Source Quality Scoring**: Compute confidence by integrating relevance, authority, and consistency

Confidence Calculation Formula:

$$\text{confidence} = \text{clip}\left(\sum_i w_i \cdot \text{score}_i - 0.03 \cdot \text{dispersion}, 0.38, 0.96\right)$$

Where weight vector $w = (0.24, 0.20, 0.16, 0.12, 0.10, 0.07)$ corresponds to: mean relevance, authority, query coverage, evidence consistency, dispersion penalty, and cross-query consensus respectively.

3.2.3 SectionSummarizerAgent **Responsibility**: Generate structured initial summaries from retrieved results

Summary Structure Template:

```
## {section_title}

### Key Points
- Point 1 [Source 1, 2]
- Point 2 [Source 3, 4]

### Key Evidence
1. Evidence description [Source: URL]
2. Evidence description [Source: URL]

### Analysis
...
```

3.2.4 ReflectionAgent **Responsibility**: Evaluate section quality, identify knowledge blind spots, weak evidence areas, and bias risks

Evaluation Dimensions:

1. **Perspective Completeness**:
   - Technical: technical principles, implementation methods
   - Social: social impact, ethical risks
   - Economic: cost-benefit, market impact
   - Regulatory: policy regulations, governance mechanisms
2. **Evidence Strength**:
   - Each claim requires support from at least 2 independent sources
3. **Bias Detection**:
   - Source concentration: single source proportion
   - Viewpoint diversity: existence of opposing viewpoints
   - Temporal bias: over-reliance on outdated information

3.2.5 SectionUpdaterAgent **Responsibility**: Update section content based on reflection results

Update Strategy: - Preserve high-confidence original content - Integrate new retrieved information to fill blind spots - Reorganize section structure for improved coherence

Confidence Gain Calculation:

$$\text{gain} = \min\left(0.08 \cdot (\text{new_quality} - 0.5) \cdot \alpha, \text{max_gain}\right)$$

Where α is the reflection sensitivity parameter (default 1.0, adjustable range 0.5-2.0), and max_gain is 0.15 for the first round and 0.10 for subsequent rounds.

3.2.6 GlobalUncertaintyAgent **Responsibility**: Aggregate uncertainties from all sections, compute global uncertainty, and provide improvement recommendations

Global Uncertainty Calculation:

$$\text{global_uncertainty} = \text{clip}\left(\bar{u} + \beta \cdot \sigma^2, 0, 1\right)$$

Where $\bar{u}$ is the weighted average uncertainty, σ^2 is the variance between section uncertainties, and $\beta = 0.08$ is the consistency penalty coefficient.

Section Weight Assignment: - Core sections (titles containing "core", "key", etc.): weight 1.3 - Auxiliary sections (introduction, appendix): weight 0.7 - Other sections: weight 1.0

3.2.7 FinalFormatterAgent **Responsibility**: Generate complete Markdown format research reports

Output Structure: - Executive Summary - Detailed analysis per section (with source citations) - Cross-section insights - Evidence strength overview - Contradiction resolution - Knowledge gap identification - Global uncertainty score - Complete reference list

3.3 Paragraph-Level Iterative Reflection Mechanism

3.3.1 Reflection Loop Flow

```
Algorithm 2: Paragraph-Level Iterative Reflection
Input: section, query, max_loops
Output: refined_section

1. section  InitialRetrieval(section, query)
2. section  InitialSummary(section)
3. loop_count  0
4. while loop_count < max_loops do
5.     evaluation  ReflectionAgent.Evaluate(section, query, loop_count)
6.     if evaluation.needs_deeper_search AND loop_count < max_loops then
7.         new_sources  SectionRetrieverAgent.SupplementarySearch(
8.             evaluation.search_suggestions)
9.         section  SectionUpdaterAgent.Update(section, evaluation, new_sources)
10.    else
11.        break
12.    end if
13.    loop_count  loop_count + 1
14.    if ConfidenceGain(section) < 0.02 then
15.        break
16.    end if
17. end while
18. return section
```

3.3.2 Reflection Trigger Conditions **Decision Rules**:

```
IF sources >= 5 AND consistency > 0.70 AND relevance > 0.65:
    threshold  0.70  // High quality: raise threshold
ELIF sources <= 3:
    threshold  0.60  // Insufficient sources: lower threshold, encourage reflection
ELSE:
    threshold  0.66  // Default threshold

needs_reflection  (sources < target) OR (confidence < threshold)
```

3.4 Uncertainty Quantification Framework

3.4.1 Uncertainty Types UPARIS-DS defines a multi-level uncertainty quantification system:

1. **Retrieval Uncertainty**
   - Relevance dispersion
   - Insufficient source diversity
2. **Content Uncertainty**
   - Insufficient evidence strength
   - Incomplete perspective coverage
3. **Integration Uncertainty**
   - Cross-section consistency
   - Unresolved conflicting viewpoints
4. **Global Uncertainty**
   - Weighted aggregation
   - Consistency penalty

3.4.2 Confidence-Uncertainty Conversion

$$\text{uncertainty} = 1 - \text{confidence}$$

Confidence range: [0.38, 0.96] (clipped) Uncertainty range: [0.04, 0.62]

3.5 Quality Evaluation Metrics

3.5.1 NDCG (Normalized Discounted Cumulative Gain)

$$\text{DCG}_k = \sum_{i=1}^{k} \frac{2^{rel_i} - 1}{\log_2(i+1)}$$

$$\text{IDCG}_k = \sum_{i=1}^{k} \frac{2^{rel_i^*} - 1}{\log_2(i+1)}$$

$$\text{NDCG}_k = \frac{\text{DCG}_k}{\text{IDCG}_k}$$

3.5.2 MRR (Mean Reciprocal Rank)

$$\text{MRR} = \frac{1}{|Q|} \sum_{q \in Q} \frac{1}{\text{rank}(q)}$$

3.5.3 Source Diversity

$$\text{diversity} = \frac{\text{unique_domains}}{\text{total_sources}}$$

---

4. Experiments and Case Study

4.1 Experimental Setup

4.1.1 Dataset We use the following test queries for system evaluation:

Category	Query	Complexity
Technology	Latest Advances in Quantum Computing	Medium
Technology	AI Ethics Governance	High
Healthcare	mRNA Vaccine Safety Assessment	High
Environment	Climate Change Impact on Agriculture	High
Economy	Blockchain Financial Applications	Medium

4.1.2 Baselines

1. **Single-Stage RAG**: Single-round retrieval + generation, no reflection mechanism
2. **ReAct-style**: Reasoning + action alternation, no multi-agent collaboration
3. **Self-Refine**: Single-agent iterative refinement, no uncertainty quantification
4. **UPARIS-DS (Full System)**: Eight agents + paragraph-level reflection + uncertainty

4.1.3 Evaluation Metrics

- NDCG@5, NDCG@10
- MRR
- Source Diversity
- Global Uncertainty
- Reflection Rounds (efficiency)
- Hallucination Rate (human evaluation)

4.2 Main Results

4.2.1 Overall Performance Comparison

Method	NDCG@5	NDCG@10	MRR	Source Diversity	Global Uncertainty	Hallucination Rate
Single-Stage RAG	0.58	0.61	0.62	0.45	0.42	23%
ReAct-style	0.63	0.67	0.68	0.52	0.38	18%
Self-Refine	0.66	0.70	0.71	0.55	0.32	14%
UPARIS-DS	**0.81**	**0.85**	**0.82**	**0.78**	**0.18**	**6%**

```

Figure 2: Uncertainty Reduction During Iterative Reflection

4.3 Case Study: "AI Ethics Governance"

4.3.1 Reflection Process Analysis Taking "AI Ethics Governance" as an example to demonstrate the actual effectiveness of paragraph-level iterative reflection:

(Initial Retrieval - First Round): - Number of retrieved sources: 3 - Confidence: 0.58 - Main sources: Primarily technical blogs

Reflection Evaluation Results:

```
Missing Perspectives:
- Regulatory perspective (EU AI Act progress)
- Industry perspective (corporate self-regulation practices)
- Public perspective (social acceptance surveys)

Weak Evidence:
- "AI Decision Transparency" lacks authoritative source support
- Insufficient "Algorithmic Bias" case studies

Bias Risks:
- Over-reliance on English sources, lacking Chinese/Asian perspectives
```

Supplementary Retrieval (Second Round): - New sources: 4 (supplementing EU AI Act, corporate AI ethics committee cases) - New confidence: 0.72 (+24%)

Final Results: - Global uncertainty: 0.15 - Source diversity: 0.82 - Reflection rounds: 2

4.3.2 Contradiction Detection and Resolution The system successfully identified and resolved the following contradiction:

Contradiction: One source claims "AI ethical risks are overhyped" while another claims "AI ethical risks urgently require governance"

System Handling: 1. List both viewpoints in the "Contradiction Resolution" section 2. Annotate evidence strength for each 3. Provide balanced analysis conclusions

---

5. Discussion

5.1 Advantages

1. **Significantly Improved Reliability**
   - Paragraph-level reflection ensures each section undergoes multi-round quality checks
   - Uncertainty quantification enables users to assess result credibility
   - Hallucination rate reduced from baseline 23% to 6%
2. **Multi-Source Knowledge Integration**
   - Cross-domain source diversity strategy ensures breadth and balance of information sources
   - Contradiction detection mechanism identifies and resolves viewpoint conflicts
3. **Intelligent Budget Allocation**
   - Reflection pressure model dynamically adjusts retrieval intensity based on confidence
   - Confidence gain convergence detection avoids ineffective iterations
4. **Interpretability**
   - Each section annotated with confidence scores and sources
   - Global uncertainty provides overall quality signals
   - Reflection process records support audit traceability

5.2 Limitations

1. **Computational Cost**
   - Eight-agent architecture incurs higher API call overhead
   - Iterative reflection extends execution time (3-10 minutes vs 30 seconds for single-round)
2. **API Dependency**
   - System depends on DeepSeek and Tavily APIs
   - Network instability may affect user experience
3. **Language Coverage**
   - Current version has relatively weaker capability for non-English queries
   - Multi-language source integration strategy needs improvement
4. **Evaluation Subjectivity**
   - Some quality assessments (e.g., "bias risk") depend on LLM judgment
   - Potential assessment bias exists

5.3 Future Work

1. **Adaptive Reflection Depth**
   - Dynamically adjust maximum reflection rounds based on query complexity
   - Introduce meta-learning to predict optimal reflection strategies
2. **Multimodal Extension**
   - Support multimodal sources such as images and PDFs
   - Integrate video and audio research reports
3. **Personalized Confidence**
   - Adjust uncertainty thresholds based on user preferences
   - Support different granularity of report outputs
4. **Distributed Deployment**
   - Develop localized deployment solutions
   - Support private knowledge base integration

---

6. Conclusion

This paper presents **UPARIS-DS** (Uncertainty-Aware Paragraph-Level Iterative Reflective Deep Search), a multi-agent deep research system built upon the MARDS-v2 framework. The system effectively addresses

hallucination, incomplete information, and insufficient knowledge integration challenges in LLM-based automated research through two core innovations: **Paragraph-Level Iterative Reflection** and **Uncertainty Quantification**.

Summary of main contributions:

1. **Designed and implemented an eight-agent collaborative architecture** with specialized division of labor, achieving efficient research pipelines
2. **Proposed the Reflection Pressure Model**, which dynamically determines whether to trigger supplementary retrieval based on confidence, achieving intelligent budget allocation
3. **Constructed a complete uncertainty quantification system** that comprehensively evaluates research quality from paragraph-level to global-level
4. **Integrated multi-dimensional quality evaluation metrics** including NDCG, MRR, and source diversity, supporting reproducible evaluation

Experiments demonstrate that UPARIS-DS achieves 23% improvement in NDCG (compared to the best baseline), reduces global uncertainty by 35%, and decreases hallucination rate from 23% to 6%, proving the effectiveness of our approach.

Future work will focus on adaptive reflection depth, multimodal extension, and personalized confidence to further enhance system practicality and generalization.
